Soil De-sealing

De Almudena Urbieta

Soil De-sealing. Biodiversity in the Factory Library. Almudena Urbieta.

De-sealing non-critical surfaces constitutes a mitigation strategy for operational and hydraulic risks. Excessive waterproofing increases thermal effects and saturates drainage systems. Ignacio and Elena analyze topographic data to identify paved areas with low utilization coefficients suitable for the restoration of soil permeability and biological functions.

Soil physics in industrial environments requires a precise balance between bearing capacity and porosity for infiltration. Elena extracts a substrate core to evaluate granular structure and biological activity. De-sealed soil functions as a biochemical reactor capable of processing light hydrocarbons and filtering particulate matter in runoff.

Interface management between daily operations and restored areas requires rigorous field analysis. Ignacio inspects the perimeter where artificial sealing converges with high-permeability zones. Managing water accumulation at these interfaces is critical to ensure the mechanical stability of the subsoil through advanced drainage engineering.

Hydrological engineering is central to technical de-sealing. Ignacio and Elena examine a drainage manhole to verify that the removal of obsolete pavements will not affect the integrity of main pipelines. The objective is to optimize the hydraulic capacity of the asset's general network by transforming linear evacuation into gradual infiltration.

The design protocol includes the selection of granular materials that maintain structural stability for the transit of logistics support vehicles. Elena supervises the installation of high-density polymer confinement cells that allow root growth without compromising necessary compaction. This technical solution ensures asset functionality and long-term pavement stability.

Occupational safety and the coordination of activities are pillars of execution. Ignacio and Elena conduct a risk control session before starting the mechanical milling of the asphalt. It is imperative that all personnel strictly comply with PPE standards and plant movement protocols to avoid operational incidents during the structural modification of the asset.

Success evaluation is based on empirical evidence and constant monitoring. Elena verifies data from moisture and temperature sensors installed in the new permeable areas. Technical audits demonstrate an improvement in the infiltration rate, validating the investment against performance indicators for structural and hydrological services.

Technical Checklist: Conduct site drainage audits, ensure load-bearing compliance, and monitor infiltration performance. Ignacio and Elena perform the final inspection of a newly converted technical permeable substrate area. The project ensures the optimization of soil management and the mitigation of environmental impact through rigorous engineering.
